

# 第一次大作业

## 实验报告

### PB20000326 徐海阳

## 1 实验要求（我完成的内容）

1. 朴素的Dijkstra算法且正确预处理数据为二进制文件（75分）
2. 将Dijkstra算法的时间复杂度降低到 $O(E \cdot \log(V))$ （4分）
3. 在（1）的基础上，成功将预处理的二进制文件的大小压缩为 $O(2 \cdot E + V)$ （5分）

## 2 设计思路

### 2.1 二进制文件

1. 简单预处理二进制文件:

先读入txt文本的ASCII码内容（以空格和换行符为终止），每个这样的字符串转换成int类型数据，再用fwrite写入到二进制文件中。大小为 $O(3E)$ 。

2. 将二进制文件大小压缩为 $O(V + 2E)$ :

顺序读入txt文件内容，用vector来存储每个V的边 $E_1, E_2, \dots, E_n$ 。在压缩文件中写入每个V，再写入它所连接的边数，再写入它的所有边。大小为 $O(V + 2E)$ 。

### 2.2 Dijkstra算法

1. 朴素算法：即书上的算法
2. 优化时间复杂度为 $O(E \cdot \log(V))$

优化的内容其实是在可以到达的边中，取权值最小边的操作。

原算法是每次都遍历所有边取最小值，优化时我们用堆排序来实现即可。

## 3 关键代码讲解

见注释，很详细。

普通压缩

```

int getnumber(FILE *fp)
{
    string str;
    char ch='2';
    int dec;
    while((ch!=' ') && (ch != 10))
    {
        fread(&ch,1,1,fp);
        str += ch;
        if(feof(fp))
            break;
    }
    str.erase(str.length()-1);
    dec = atoi(str.c_str());
    return dec;
}

void write(FILE *sfp, FILE *dfp)
{
    int number;
    number = getnumber(sfp);
    fwrite(&number,sizeof(int),1,dfp);
}

```

优化压缩

```

vector<vector<int>> vec(MAX+1, vector<int>()); //用到vector
sfp = fopen("Data Structure 2021 fall\\lab 3\\distance_info.txt","r");
dfp = fopen("Data Structure 2021 fall\\lab 3\\zippro","wb");
while (!feof(sfp))
{
    v1 = getnumber(sfp);
    v2 = getnumber(sfp);
    w = getnumber(sfp);
    vec[v1].push_back(v2);
    vec[v1].push_back(w);
}
fclose(sfp);
input = MAX;
fwrite(&input,sizeof(int),1,dfp); //写入总节点数
for(i=1;i<=MAX;i++)
{
    length = vec[i].size()/2;
    fwrite(&length,sizeof(int),1,dfp); //写入该节点边数
    for(auto j=vec[i].begin();j<vec[i].end();j++)
    {
        input = *j;
        fwrite(&input,sizeof(int),1,dfp);
    }
}
fclose(dfp);
printf("ALL is OK");
return 0;

```

Dijkstra算法

```

bool Dijkstra(int S, int T)
{
    int length = 0;
    //cout << vex_num << "*" << endl;;
    for (int i = 1; i <= MAXVEX; i++) {
        node[i].dist = INF; node[i].vis = false;
        //cout << head[i] << " ";
    } //初始化点信息
    node[S].dist = 0;
    Vitality_node p = { S, 0 };
    struct Vitality_node *Q;
    Q = (Vitality_node*)malloc(sizeof(Vitality_node));
    Q->next = nullptr;

    p.next = Q->next;
    Q->next = &p;
    length ++;

    while (Q->next) {
        Vitality_node *min = QSort1(Q);
        Vitality_node t = *min;
        Q->next = Q->next->next; //Pop(Q)
        int u = t.pos;
        if (node[u].vis) continue;
        if (node[u].dist == INF || u == T) break; //优化常数项，评分细则（4）
        node[u].vis = true; //u是目前到达的最短处，从这个点向外松弛
        for (int i = head[u]; i != 0; i = edge[i].next) { //更新最短路径
            int now = edge[i].v;
            //cout << node[now].dist << " ";

            if ((node[now].dist > node[u].dist + edge[i].w) && !node[now].vis) {
                node[now].dist = node[u].dist + edge[i].w;
                node[now].last_node = u; //记录前驱节点
                p = { now, node[now].dist };
                p.next = Q->next;
                Q->next = &p;
                length ++;
            }
        }
    }

    if (node[T].dist == INF) return false;

    printf_s("The shortest path's length from Src to Dst is: %d\n", node[T].dist);

    int t = T;
    printf_s("The shortest path from Dst to Src is:\n");
    while (t != S) {
        printf_s("%d<- ", t);
        t = node[t].last_node;
    }
    printf_s("%d\n", t);
    return true;
}

```

Dijkstra优化算法

```

bool Dijkstra(int S, int T)
{
    priority_queue<Vitality_node> Q; //记录节点编号 评分细则 (2)
    //cout << vex_num << "*" << endl;;
    for (int i = 1; i <= MAXVEX; i++) {
        node[i].dist = INF; node[i].vis = false;
        //cout << head[i] << " ";
    } //初始化点信息
    node[S].dist = 0;

    Vitality_node p = { S, 0 };
    Q.push(p);
    while (!Q.empty()) {
        Vitality_node t = Q.top();
        Q.pop();
        int u = t.pos;
        //cout << node[u].dist << " ";
        if (node[u].vis) continue;
        if (node[u].dist == INF || u == T) break; //优化常数项, 评分细则 (4)
        node[u].vis = true; //u是目前到达的最短处, 从这个点向外松弛
        for (int i = head[u]; i != 0; i = edge[i].next) { //枚举这个点的所有邻边
            int now = edge[i].v;
            //cout << node[now].dist << " ";
            if ((node[now].dist > node[u].dist + edge[i].w) && !node[now].vis) {
                node[now].dist = node[u].dist + edge[i].w;
                node[now].last_node = u; //记录前驱节点
                p = { now, node[now].dist };
                Q.push(p); //入队
            }
        }
    }
}

```

## 4 调试分析

调试正常

test2:

[illegible]

[illegible]

在朴素dijkstra算法的情形下：算法执行时间为：70.231s（输出略）

在改进 (2) 中: 算法执行时间为: 17.483s (输出如上图)

## 6 实验总结

1. 完成二进制的压缩，以及压缩的优化
2. 完成dijkstra朴素算法
3. 完成基于堆排序的dijkstra优化算法
